Xgard Bright Public Modbus Interface

Doc No.	BJ-ENG-0006
Issue No.	v1.2
Date	24/07/2015
Prepared By:	Echo.Xue
Approved By:	

1. Introduction

This document describes the public modbus interface for the XgardBright product. This document is suitable for distribution to customers.

Engineering Document

Xgard Bright Public Modbus Interface

Doc No.	BJ-ENG-0006
Issue No.	v1.2
Date	24/07/2015
Prepared By:	Echo.Xue
Approved By:	

2. Modbus Interface

Refer to [1] and [2] listed in the Reference section for details of the Modbus protocol. This document does assume basic knowledge of the Modbus protocol.

The XgardBright has a standard implementation of modbus. The section describes specific details of the implementation for XgardBright.

The XgardBright is always addressed as a slave device.

2.1. Slave Address

At power-on the XgardBright will always initialise itself from the NV mem stored inside. This address can be changed by following the menu operation built in XgardBright.

2.2. Electrical

The XgardBright will always initialise (at power-on) to the data format described below:

Data format: 1 start bit
 8 data bits, least significant bit first no parity bit
 2 stop bits

Transmission mode: RTU (Remote Terminal Unit)

Error check: cyclic redundancy check (CRC)

Baud rate: 9600.

Message turn-around delay: 50mS turn around delay (guaranteed minimum) – this is an extension to standard modbus.

Data encoding: ‘big-Endian’ representation for addresses and data items. This means that when a numerical quantity larger than a single byte is transmitted the most significant byte is sent first.

Engineering Document

Xgard Bright Public Modbus Interface

Doc No.	BJ-ENG-0006
Issue No.	v1.2
Date	24/07/2015

Approved By:	

2.3. Packet Format

All MODBUS packets are composed of data bytes and have the following format:

Byte	Contents	Range
1	Address of slave	1-247
2	Function code	
3 . . .N	Variable length data field	
N+ 1	CRC low byte	
N+ 2	CRC high byte	

2.4. 2.4 Packet Types

2.4.1. Query Packet

A query packet is a packet generated by the bus master and addressed to a slave unit.

2.4.2. Acknowledge Packet

If the bus master generates a query packet addressed to a device, the device will generate an acknowledge packet, which contains a response to the query.

The acknowledge packets contents is specific to each function code and each is defined later.

If the packet from the master is incorrect in some way then the acknowledge packet is replaced by an exception packet see below.

2.4.3. Exception Packet

The following circumstances will cause an exception packet to be generated in response to a query packet. The exception packet contains the exception error code shown in the table.

Engineering Document

Xgard Bright Public Modbus Interface

Doc No.	BJ-ENG-0006
Issue No.	v1.2
Date	24/07/2015
Prepared By:	Echo.Xue
Approved By:	

Exception Error	Probable Causes of the Exception
No response	<p>The MODBUS master has sent a data packet with an incorrect MODBUS address to the XgardBright unit.</p> <p>The MODBUS master has sent a data packet with an incorrect CRC to the XgardBright unit.</p>
Illegal Function	<p>The MODBUS master has sent a data packet to the XgardBright unit that contains a function code, which the XgardBright unit is not programmed to respond to i.e. anything other than codes 0x03 or 0x10.</p>
Illegal Data Address	<p>A MODBUS master has attempted to access register indexes that are beyond the bounds specified for the product.</p> <p>The MODBUS master sends a query packet that attempts to access data that is inaccessible in their current role (either read or write).</p> <p>The MODBUS master has attempted to write to a read only register.</p>
Illegal Data Value	<p>The data associated with a register write operation is incorrectly sized i.e. the MODBUS master sent 5 words when the controller expected only 4.</p> <p>The data supplied with the query packet is out of range.</p>
Slave Device Busy	<p>The packet is correct in every aspect but the slave unit is incapable of acting on the packet at the present time e.g. write to FRAM when FRAM is busy.</p>
Slave Device Failure	<p>The packet sent to the XgardBright unit is correct in every aspect but the slave unit has just become faulty.</p>

The associated exception packet is simply a packet echoing back the slave address and the function code of the query packet but with the most-significant bit of the function code set, followed by an error code, followed by the CRC. For example if a query packet with function code 0x03 were received which has an error then the exception packet would take the form of:

Engineering Document

Xgard Bright Public Modbus Interface

Doc No.	BJ-ENG-0006
Issue No.	v1.2
Date	24/07/2015
Prepared By:	Echo.Xue
Approved By:	

Byte	Contents	Range
1	Address of Slave	1-247
2	Function Code with MSBit set.	0x83 (hex)
3	Exception Error Code	
4	CRC low byte	
5	CRC high byte	

If an exception occurs for any part of a message then the entire message is discarded. Therefore, if a multiple register write raises an exception, none of the message will be processed.

2.5. Implemented Function Codes

XgardBright only recognises a limited number of function codes, as elaborated in the table below:

Function Code	Function code Definition
3	Read Holding Registers
16	Write Multiple Registers

2.6. Read Holding Registers (Function Code 0x03).

Data format from MODBUS Master:

Byte	Contents	Range
1	Address of slave	1-247
2	Function code	3
3	Starting register high byte	
4	Starting register low byte	
5	Number of registers (N) high byte	
6	Number of registers (N) low byte	
7	CRC low byte	
8	CRC high byte

Response from XgardBright Unit:

Byte	Contents	Range
1	Address of slave	1-247
2	Function code	3
3	Byte count (n) of data that follows* (excluding CRC).	
4	First register data high byte	
5	First register data low byte	
	Repeats for number of registers read	
4 + n	CRC low byte	
5 + n	CRC high byte	

2.7. Preset Multiple Registers (Function Code 0x10)

Data format from MODBUS Master:

Byte	Contents	Range
1	Address of Slave	1-247
2	Function Code	16 (decimal)
3	Starting Register High Byte	
4	Starting Register Low Byte	
5	Number of Registers High Byte	
6	Number of Registers Low Byte	
7	Byte Count of Data (n) excluding CRC	
8	First Register data High Byte	
9	First Register data Low Byte	
..		
..		
8 + n	CRC Low Byte	
9 + n	CRC High Byte

Response from XgardBright Unit:

Byte	Contents	Range
1	Address of Slave	1-247
2	Function Code	16
3	Starting Register High Byte	
4	Starting Register Low Byte	
5	Number of Registers Preset High Byte	
6	Number of Registers Preset Low Byte	
7	CRC Low Byte	
8	CRC High Byte	

2.8. Data Timing

Standard MODBUS defines a silent interval of 3.5 character times to delimit data packets. However, a silent interval of 5mS is used to define the termination of a data packet – this assists PC software in interpreting data packets.

The error condition described in [1] when there is a delay of 1.5 character times, but less than 3.5 character times between data, is not implemented – this can, apparently, cause problems with legacy systems and PC timings.

On receipt of a message requiring a response, the instrument will pause for a guaranteed period of at least 50mS before transmission will commence. Again, there may be timing problems on PC systems if this restriction is not applied.

2.9. Modbus Data Types

The following data types may be used:

UINT16	Two bytes, unsigned integer (16 bits), one word long, most significant byte first.
UINT32	Four bytes, unsigned integer (32 bits), 2 words, most significant word first.

Engineering Document

Xgard Bright Public Modbus Interface

Doc No.	BJ-ENG-0006
Issue No.	v1.2
Date	24/07/2015
Prepared By:	Echo.Xue
Approved By:	

BIT32	Four bytes, each bit signifying a different status or code.
STRING nn	Text string, nn characters long, packed 2 characters per word, of length nn/2 words. Ordered with first character in high byte of first word. Null padded in least significant byte of last word if needed.
FLOAT	Floating point number, in IEEE-754 format.
ENUM	Data enumeration. A UINT16 where each number (counting from 0) refers to an option from a list of possibilities. In the Register map notes below, enumerations and their meanings are listed and may be different for read and write operations on the same register.

2.10. Register Permissions

It is not necessarily possible to read or write every register in the modbus register map. The permissions used in the modbus map are:

R/W Read and write allowed. (Holding Registers)

R Read only. The information cannot be modified via Modbus (Input Registers).

2.11. Note on Message Processing

It is always guaranteed that registers in a message will be processed sequentially from message start to message end. The XgardBright Host has a 256 byte modbus buffer. This buffer is large enough to contain the largest valid modbus message.

2.12. Modbus Start-up Response

The XgardBright will respond to modbus as soon as it has reset. This allows for immediate polling of identification registers
1 to 6 (inclusive).

The XgardBright will immediately enter an initialisation phase. During this phase other registers in the map will be populated. Unpopulated data will read as 0. This phase can be detected by reading register 100. It will return 65535 (or

0xffff in hexadecimal) whilst initialisation is in progress.

The next phase is warm-up. This is normally 30 seconds. During this phase the instrument will be in start-up inhibit mode. During the warm-up phase the instrument cannot be gas zeroed or calibrated (as the XgardBright is waiting for the gas readings to stabilise). Analogue output adjustment (zero trim, span adjustment) is still possible during the warm-up phase. It is not possible to control inhibit mode whilst the XgardBright is in start-up inhibit mode.

Once the warm-up phase is completed the instrument will operate normally.

For further information on inhibit see the note on inhibit in section 9, Analogue Output.

3. Modbus Data Model

As described by reference [1], elements in the modbus data model start from 1, whilst the data elements that are referred to by this data model start from 0. Crowcon generally refers to the elements in the data model as registers.

The standard Modbus specification [1] talks of 16 bit (one word) registers and numbers of data bytes. The interpretation of registers and words used in this document (and used by other Crowcon products using Modbus, but perhaps with different terminology) is as follows:

A register will refer to the address of a piece of data within the register map. A register may consist of one or more 16-bit words. Registers are uniquely identified by their register address.

The size of a register (sometimes also confusingly referred to as the number of registers) - that is the amount of data at a particular register address - is referred to by the number of words it contains.

Restated, we have uniquely addressed registers referring to one or more words of data.

Holding registers and Input registers are often referred to in the range 4XXXX. In the terminology used in this document, register 1 would be referred to as 40001 and would be addressed as register 0000 in the data address field of the modbus message. The '4XXXX' reference is implicit in this modbus data model.

This will be made clear by the example messages and responses given in section 7, Example Modbus Messages.

3.1. Identification Data

Basic identification of instrument.

Register	Name	Words	R/W	Data Type	Notes
1	Instrument identification	8	R	STRING16	"Xgard Bright"
2	Manufacturer	8	R	STRING16	"Crowcon"
3	Software version of Host (instrument)	8	R	STRING16	"V1.2"
4	Serial number of Host (instrument)	8	R	STRING16	

Engineering Document

Xgard Bright Public Modbus Interface

Doc No.	BJ-ENG-0006
Issue No.	v1.2
Date	24/07/2015
Prepared By:	Echo.Xue
Approved By:	

5	Date of manufacture	2	R	STRING8	seconds from 1/1/1970
---	---------------------	---	---	---------	-----------------------

3.2. Runtime Data

Live instrument data. Data is updated 1/second.

Register	Name	Words	R/W	Data Type	Notes
1001	Gas level	2	R	FLOAT	
1002	Warm-up/initialisation state	1	R	UINT16	0=operational; n=seconds or warm-phase remaining;
1003	Supply voltage	2	R	FLOAT	In mV
1004	Temperature	2	R	FLOAT	See later section, Status Flags
1005	Analogue output feedback	2	R	FLOAT	In /mA by instrument type
1006	Inhibit status	1	R	ENUM 2	0=operational;1=inhibited
1007	Raw signal level	1	R	UINT16	

Register 1001, gas level, represents the level actually output by the instrument (on the analogue output). Normally this will be the gas level. When the instrument is some alternate mode (e.g. inhibit, warning due to obscuration) then this register will give the gas level that corresponds to the analogue output. For example, for a 0 to 100% LEL instrument with the obscuration warning level set to -12.5% (of output range, or 2mA) then when the unit is obscured the analogue output will give 2mA and register 101 will respond with -12.5. For a 0 to 20% LEL instrument with the obscuration warning level set to -12.5% (of output range, or 2mA) then when the unit is obscured the analogue output will give 2mA and register 999 will respond with -2.5%. The status of the instrument should always be polled along with the measured as level. See the section on Status Bits and Severity Level later in this document. If there are status bits with severity level other than OK then the gas level read in register 999 may not be reliable.

3.3. Gas Configuration

Information on gas (and range), and zero and calibration control and information.

Register	Name	Words	R/W	Data Type	Notes
200	Gas name	8	R	STRING8	
201	Gas units	8	R	STRING8	
202	Gas range	2	R	FLOAT	
203	Gas zero control	1	R/W	ENUM	Write: 0=do nothing;1=zero module Read: 0=ok;1=busy;

Engineering Document

Xgard Bright Public Modbus Interface

Doc No.	BJ-ENG-0006
Issue No.	v1.2
Date	24/07/2015
Prepared By:	Echo.Xue
Approved By:	

204	Time of last zero	2	R/W	UINT32	Recommended data: seconds from 1/1/1970
205	Last zero performed by	8	R/W	STRING8	
206	Gas calibration level	2	R/W	FLOAT	In measurement units
207	Gas calibration control	1	R/W	ENUM	Write: 0=do nothing;1=calibrate module Read: 0=ok;1=busy;
208	Time of last calibration	2	R/W	UINT32	Recommended data: seconds from 1/1/1970
209	Last calibration performed by	8	R/W	STRING8	

To perform a zero write 1 to the Gas Zero register. Poll the register to check the result of the zero operation. The last zero time and last zero operator registers are for information only and can be written with any compatible information desired. A successful zero will always set the last zero time to 0 and the last zero operator data to all 0's

To perform a calibration write the desired calibration level to the Gas calibration level register then write 1 to the Gas calibration control register. Poll the register to check the result of the calibration operation. The last calibration time and last calibration operator registers are for information only and can be written with any compatible information desired. A successful calibrate will always set the last calibration time to 0 and the last calibration operator data to all 0's.

It would be usual to place the instrument into inhibit mode before applying gas to calibrate an XgardBright and to remove inhibit mode once the calibration gas has been purged from the instrument.

The Zero/calibration operation complete timer register gives the number of seconds until the zero/calibration operation is complete. If an error that invalidates the zero/calibration operation occurs whilst the operation is in progress then this register will immediately revert to 0 to indicate the operation has completed. No matter what this register does, always poll the Gas zero control or Gas calibrate control (as appropriate) to determine the result of the zero/calibration operation.

3.4. Alarm Configuration

Register	Name	Words	R/W	Data Type	Notes
400	Alarm 1	2	R/W	FLOAT	>0.0, in measurement units
401	Alarm 2	2	R/W	FLOAT	>0.0, in measurement units

Engineering Document

Xgard Bright Public Modbus Interface

Doc No.	BJ-ENG-0006
Issue No.	v1.2
Date	24/07/2015
Prepared By:	Echo.Xue
Approved By:	

Alarms should be configured so that alarm 2 > alarm 1. If new alarm levels are set then the changed alarm level will be saved automatically by the instrument.

Alarms only set status bits when triggered. Alarms will be triggered at the configured alarm level, and will clear at 1 measurement unit below the configured alarm level.

4. Exception Codes

This section gives a general description of the Modbus error codes as they relate to the XgardBright:

Code	Name	Meaning
1	Illegal function	Function code not supported (i.e. not 3 or 16), see section 2.3, Implemented Function Codes
2	Illegal data address	invalid/unknown register address, invalid number of registers, invalid number of words for the specified registers, write to read only register
3	Illegal data value	Number out of range – the registers are valid, but an attempt is being made to put invalid data into the register.
4	Slave device failure	Not implemented.
5	Acknowledge	Not implemented.
6	Slave device busy	Attempt to perform an action that cannot be performed at this time – e.g. attempt to adjust inhibit mode whilst still in start-up inhibit.
7	Negative acknowledge	Not implemented.

5. Zero and Calibration Status Codes

Code	Explanation
OK	Operation completed successfully.
Busy	Still busy from previous zero or calibration request – try again in few seconds.
Warm-up	Instrument still in start-up warm-up phase – check Warm-up/initialisation state and try again when completed.
Signal error	Raw detector reading under/over range – instrument is in fault, return to Crowcon for servicing.
Gain warning	Not implemented in XgardBright.
Lamp failure	Failure of gas or reference lamp detected at lamp start-up or during lamp calibration process – instrument is in fault, return to Crowcon for servicing.
Detector failure	No measureable output from the detector. Check that the gas chamber is not completely blocked. If it is clear it, otherwise the instrument is in fault, return to Crowcon for servicing.

Engineering Document

Xgard Bright Public Modbus Interface

Doc No.	BJ-ENG-0006
Issue No.	v1.2
Date	24/07/2015
Prepared By:	Echo.Xue
Approved By:	

Obscured	Obscuration level exceeds defined error level. Refer to Operating Instructions for corrective action.
Insufficient gas	It does not look like sufficient gas has been applied to instrument. Check applied gas and configured calibration level is correct. Try re-zeroing instrument before calibration.
Gain error	Not implemented in XgardBright.
Gain low	Applied gas level is too high. Check applied gas and configured calibration level is correct. Try re-zeroing instrument before calibration.
Gain high	Applied gas level is too low. Check applied gas and configured calibration level is correct. Try re-zeroing instrument before calibration.
Prod. cal. error	Instrument requires servicing. Please return to Crowcon with a full explanation of the problem.
Error in iModule response	Internal fault in XgardBright – instrument is in fault, return to Crowcon for servicing.
Generic failure	Backwards compatibility error. Will never occur in XgardBright.

6. Example Modbus Messages

6.1. Read Gas Level

Read register 100, 2 words. Sent message:

01 03 03 E6 00 02 55 BA

Response:

01 03 04 3F 0C 66 E5 DC 0F

This equates to a gas level of 0.55% LEL
